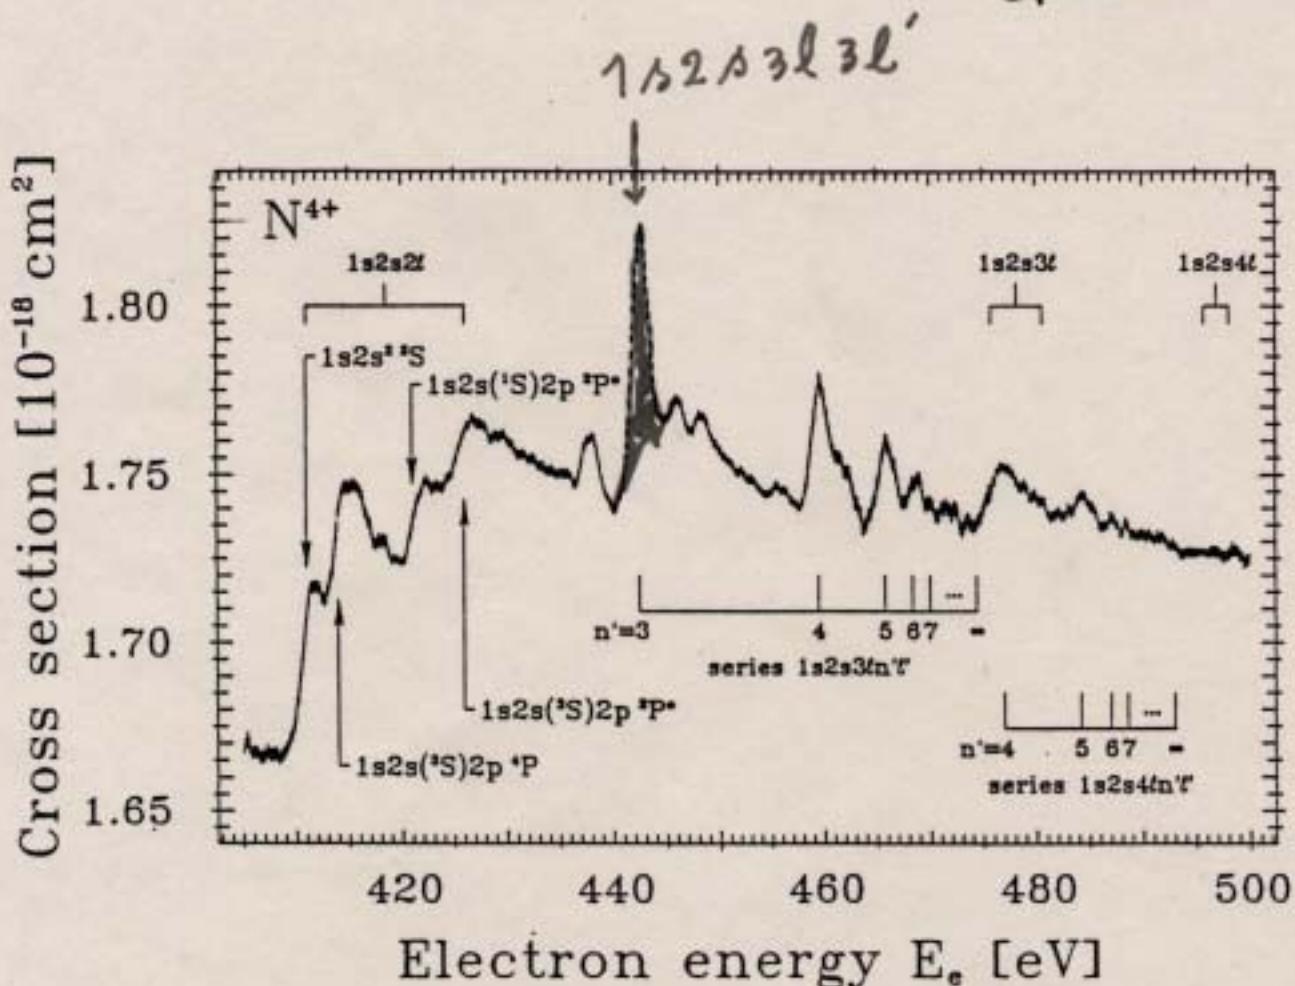

Figure 11. Cross sections for indirect contributions to electron impact ionization of Li-like N^{4+} ions¹⁸. The scan data were smoothed over bins of seven adjacent points of the original measurement. Assignments of states to the observed features are given on the basis of calculations using the code of Grant et al.¹⁹. Two series of Rydberg states involving $\Delta n = 2$ and $\Delta n = 3$ transitions can be recognized: $1s2s3nl$ ' ($n = 3, 4, 5, 6, \dots$) and $1s2s4nl$ ' ($n = 4, 5, \dots$). The series limits $1s2s3l$ and $1s2s4l$ are at the thresholds for direct inner-shell excitations. The ranges of corresponding energy levels¹⁷ are indicated.

The new measurements reveal even more structure than might have been expected simply on the basis of the model calculation²² for a Na-like ion shown in Fig. 9. Apparently there are other resonance series and steps and dips in the cross section which make it difficult to see a clear excitation-autoionization feature. The resonance contributions (the snow) appear to be much higher than the excitation steps (the stairs) on top of which they are observed. One particular series of resonances between 51 eV and 55 eV is interpreted to be due to $2p^3 3s 3pnl$ configurations; i. e. the Rydberg series corresponding to the one in Fig. 9. Peaks up to $n = 6$ are resolved, the higher Rydberg states lump together due to the limited energy resolution of the experi-

ment. An upper limit of 0.3 eV to the energy spread is set by the width of the resonance observed at 55.5 eV. The strongest REDA peak observed makes up for about 3.5 % of the total ionization cross section at that particular energy. By this measurement a first experimental step is made towards the old challenge to see REDA processes in sodium-like Fe^{15+} ions.

Strong REDA resonances have also been found in the ionization of lithium-like ions²⁷⁻²⁸ B^{2+} , C^{3+} , N^{4+} , O^{5+} and F^{6+} . A scan measurement on N^{4+} is shown in Fig. 11. Details in the vicinity of the excitation-autoionization threshold were studied (see also Fig. 7). Individual terms of the $1s2s2l$ excited configurations are resolved. In addition many resonance features are found.

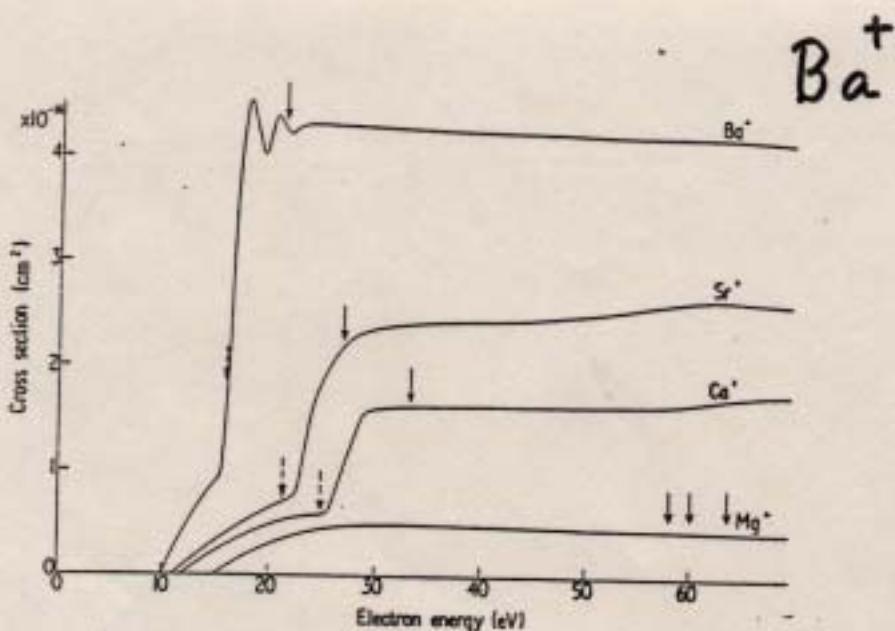

Figure 1. Observed ionization functions for the ground states of Ba^+ , Sr^+ , Ca^+ and Mg^+ . The experimental results for Sr^+ and Ca^+ are from Peart and Dolder (1975), also the figure is taken from their paper, while the results for Ba^+ and Mg^+ are from Peart *et al* (1973) and Martin *et al* (1968), respectively. For Ba^+ , Sr^+ and Ca^+ , the calculated (p^1d^1P) s^2P (broken arrows) and (1P) s^2P (arrows) thresholds are indicated. For Mg^+ , the $2p^2(3d3s^2D)^2P$, $2p^2(3d3s^3D)^2P$ and $2p^2(3d3s^1D)^2P$ thresholds, in order of increasing energy, are shown. The $2p^2(3p^2^1D)^2P$ and $2p^2(3d3s^1D)^2P$ terms are strongly mixed as explained in the text.

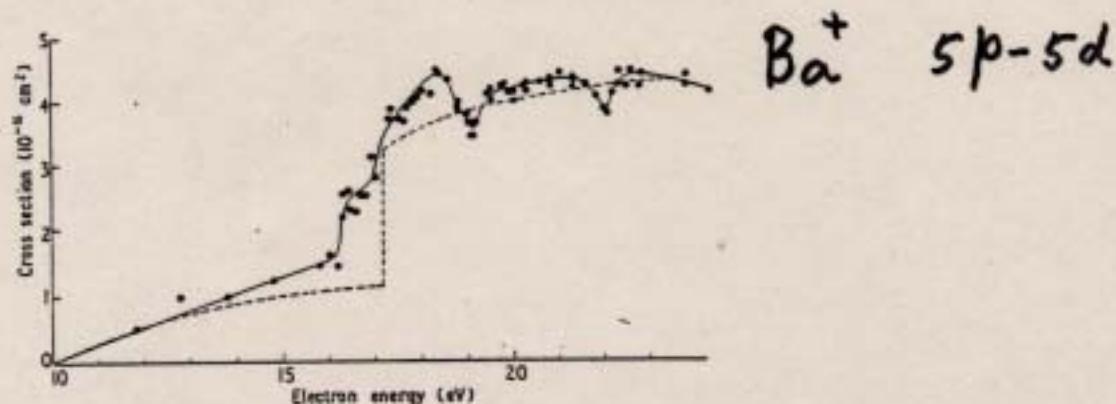

Figure 1. Cross sections for the ionization of Ba^+ plotted against incident electron energy. Autoionization thresholds are resolved at energies of 15.8, 16.8, 19.2 and 21.9 eV. --- results of calculations by Bely *et al* (1971).

拡がりは約2.9eVである。両ビームはチョッピングされており、両方のビームが出ているときの真空は、 1×10^{-9} Torr以下に保たれている。

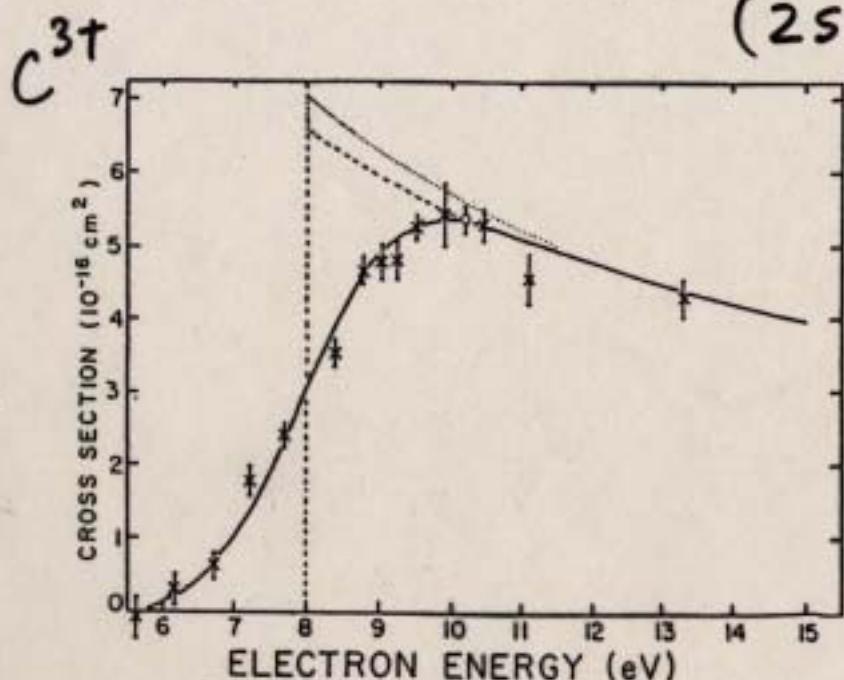

Fig. II - 3 - 5. Cross section vs electron energy for $e^+ + C^{3+}(2^2S_{1/2}) \rightarrow e^+ + C^{3+}(2^2P_{1/2, 3/2})$. Open circle is an absolute measurement. Crosses are measured relative to the open circle. The dashed curve: two-state close-coupling (Ref. 10). Dotted curve: unitarized Coulomb-Born with exchange (Ref. 10). Solid curve: "expected" cross section (see text) resulting from convolution of electron energy distribution with the two-state close-coupling calculation. Bars represent statistical uncertainties at 90% confidence level. There are additional systematic uncertainties totaling $\pm 17\%$ at "good confidence level" (see text).

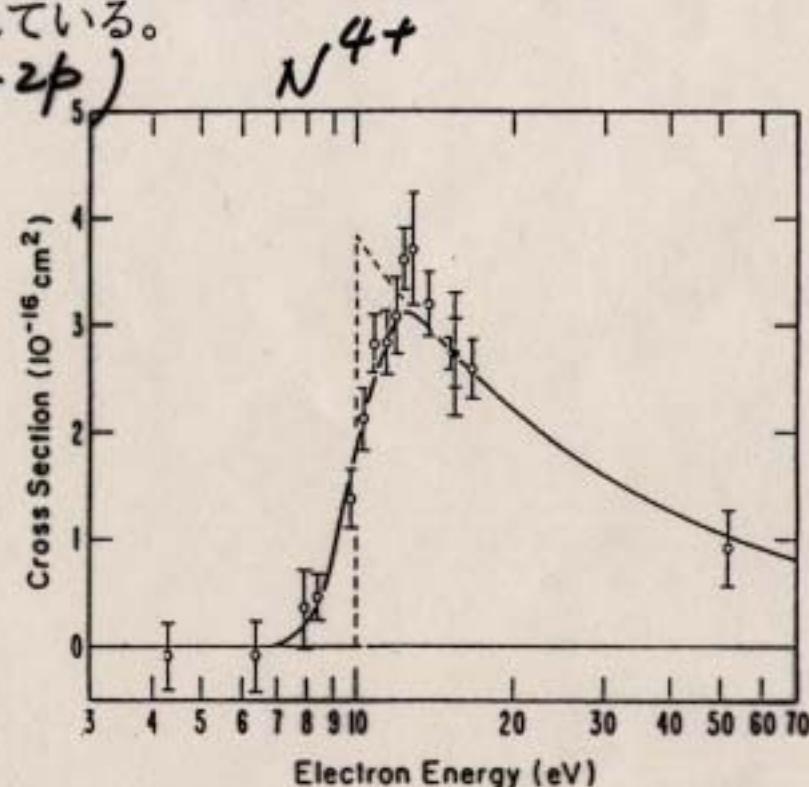

Fig. II - 3 - 6. Absolute cross section vs electron energy for $2s-2p$ excitation of N^{4+} by electron impact. Solid point at 15.5 eV represents an absolute measurement, relative to which open points at other energies were measured. Dashed curve represents two-state close coupling with exchange calculation (2CCX) from Ref. 19, and solid curve is a convolution of the experimental electron energy distribution with the dashed curve. Bars on experimental points designate random uncertainties at 90% confidence level, and outer bars on solid point represent the total experimental uncertainty at good confidence level (see Table I and text).

Zn^+ (4s-4p)

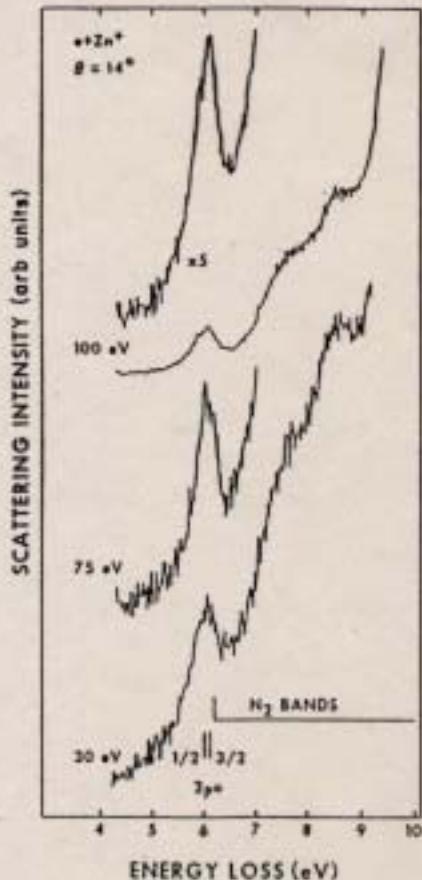

Fig. III-14. Experimental energy-loss spectra of the $^3S_{1/2} - ^3P_{1/2}$ resonance transition in Zn II at $\theta = 14^\circ$ scattering angle, 6-keV ion energy, and at the indicated electron energies. Energy-loss transitions in molecular N_2 are responsible for the rising background. The onset of these transitions [the (0,0) band of the $X \rightarrow A$ Vegard-Kaplan system] is shown.

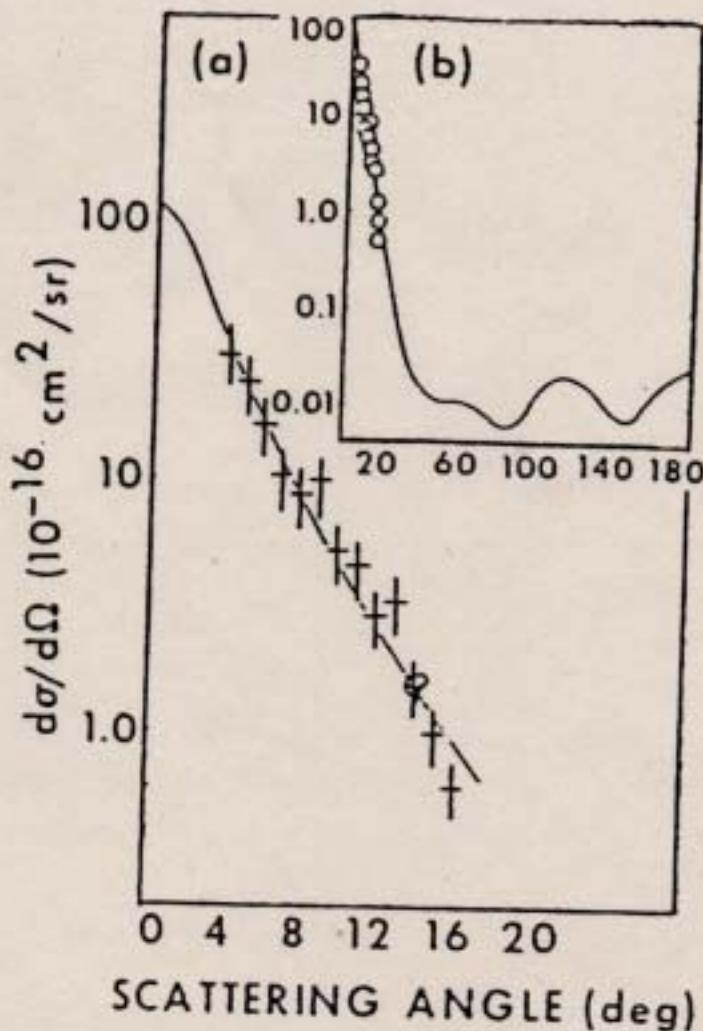

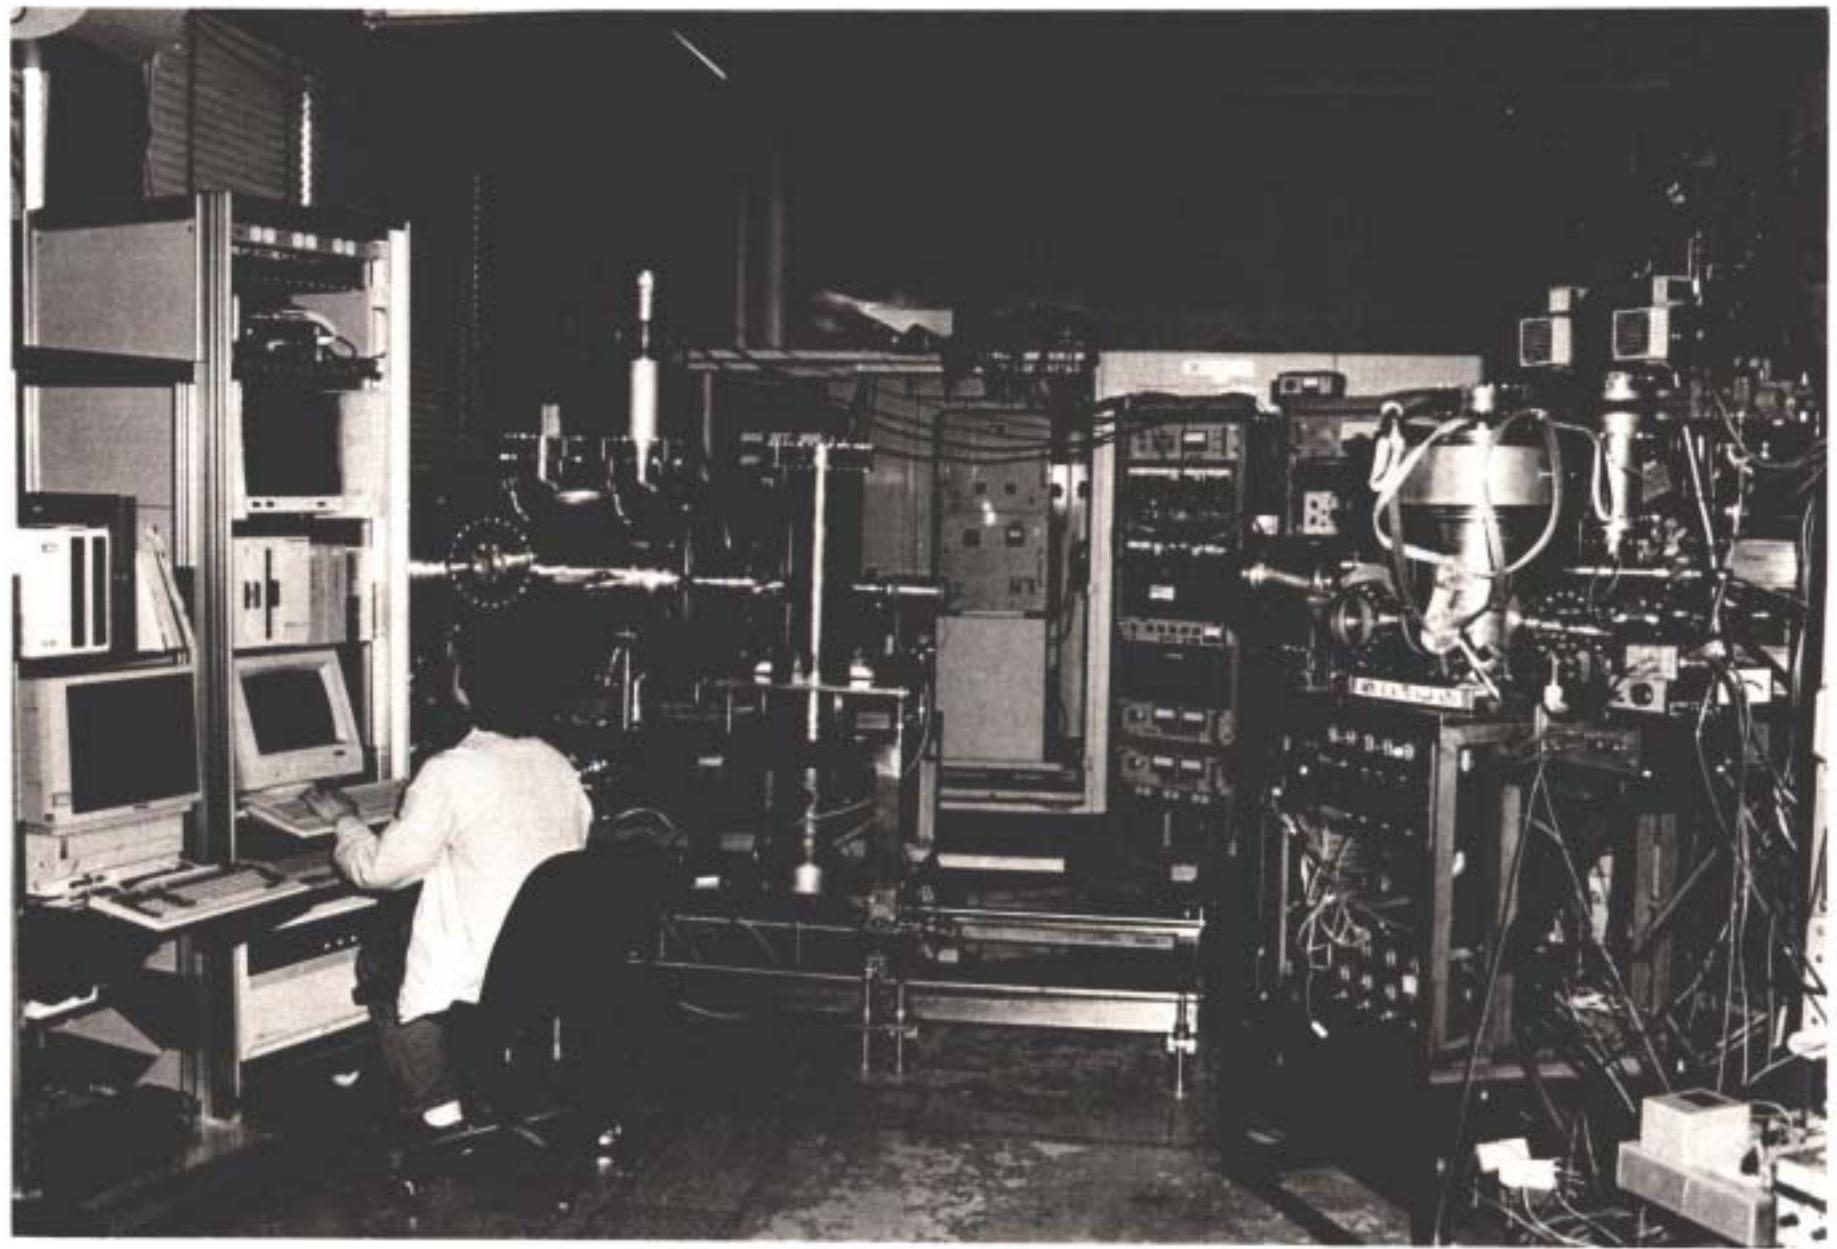

Table 1. Relative and absolute differential cross sections for excitation of the resonance transition $^3S_{1/2} \rightarrow ^3P_{1/2,3/2}$ in Zn II at $\theta = 14^\circ$.

Electron energy (eV)	Relative cross section	Absolute cross section ($10^{-17} \text{ cm}^2/\text{sr}$) ^a
30	1.32 ± 0.24	4.63
40	1.89 ± 0.34	6.63
50	1.46 ± 0.26	5.13
60	2.53 ± 0.40	8.88
75	2.83 ± 0.31	9.93
85	3.69 ± 0.37	13.0
100	2.58 ± 0.21	9.05

^aWith an error estimate of 33%.

Toroidal analyzer

It consists of a pair of toroidal deflectors and lenses.
Entrance slit is 1 mm wide and circularly extended.

Conditions

✓ Residual gas pressure

Base pressure	$< 1 \times 10^{-10}$ Torr
Both beams ON	1.4×10^{-10} Torr

✓ Ion beam (Ar^{q+} , $q = 7, 8$)

Energy	$15 \times q$ keV
Current	$1.5 \mu\text{A}$
Diameter (FWHM)	0.5 mm ϕ

✓ Electron beam

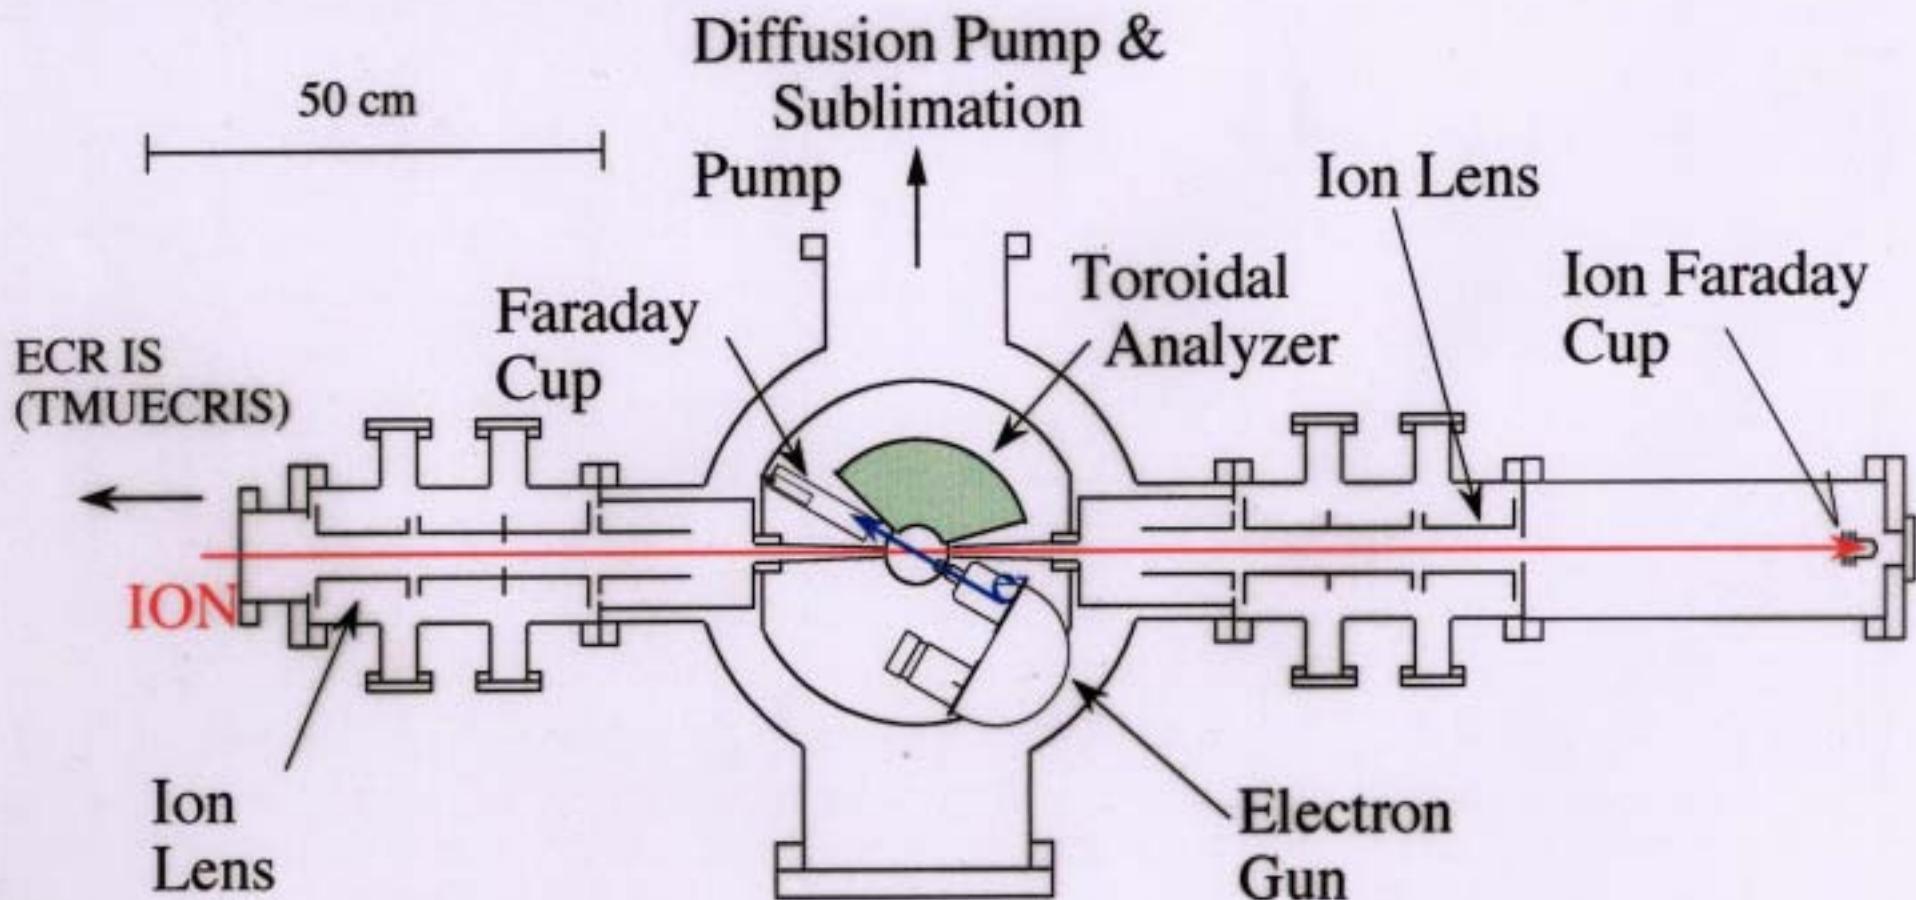

Energy	80.0 eV (Ar^{7+}), 78.6 eV (Ar^{8+})
Current	$1.5 \mu\text{A}$
Diameter (FWHM)	0.5 mm ϕ

✓ Collision energy (CM) 100 eV

✓ Toroidal analyzer

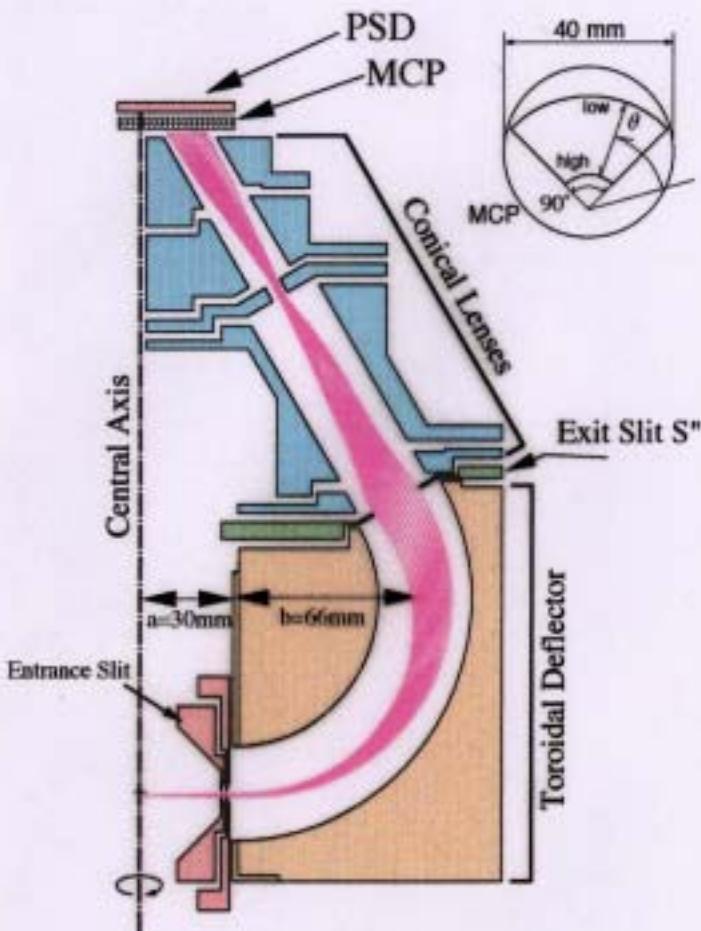

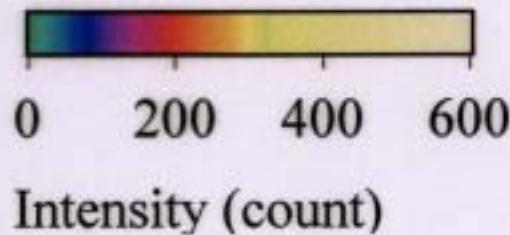

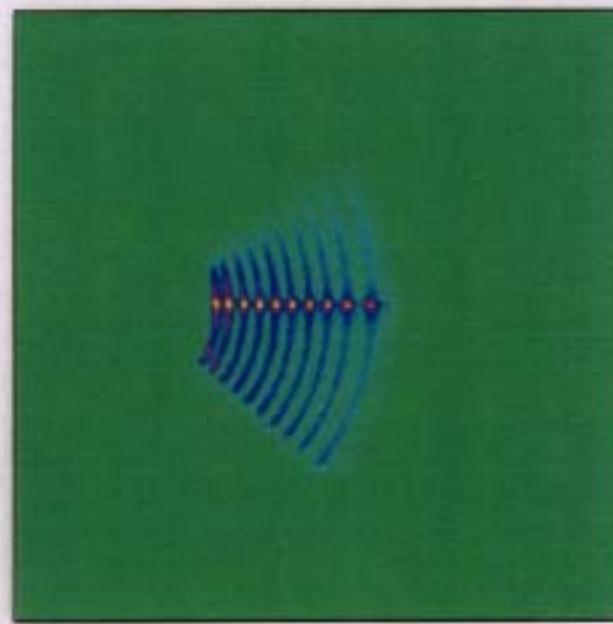

Pass energy (E_{pass})	100 eV (small angle)
	110 eV (large angle)
Angular range	$30^\circ - 120^\circ$
Energy range	$0.9E_{\text{pass}} - 1.1E_{\text{pass}}$
Relative energy resolution	1 %

xperimental setup

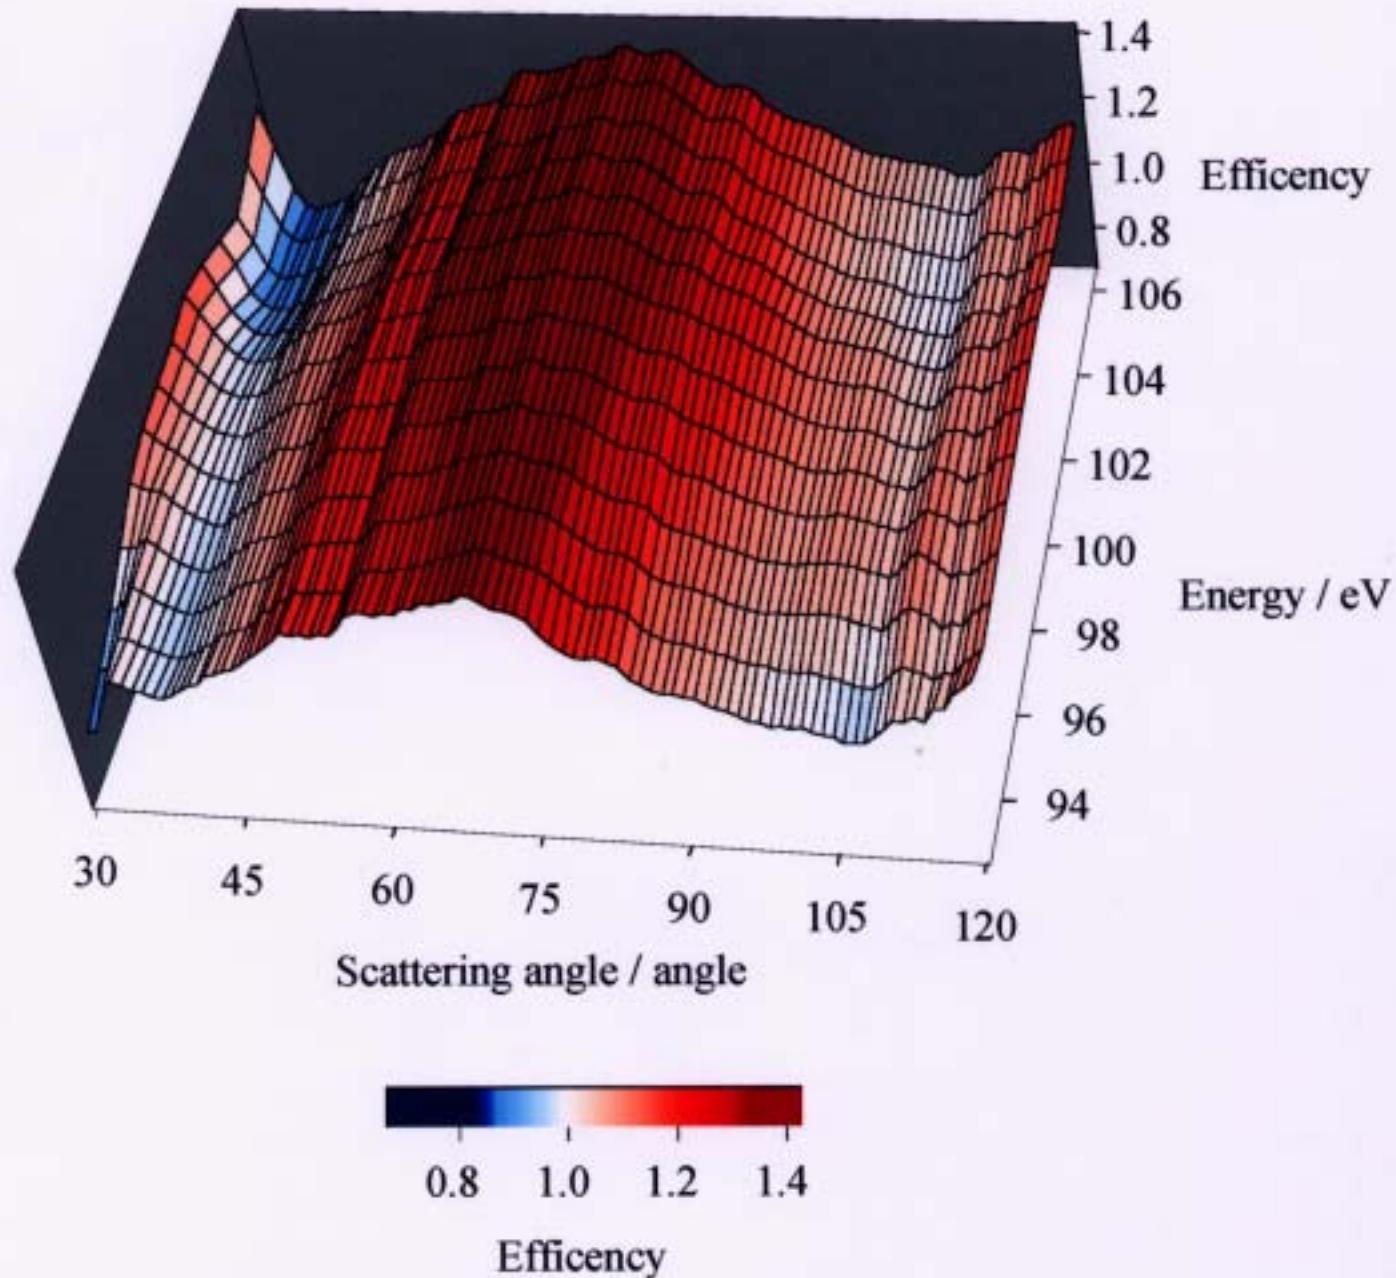

Ions are extracted from 14.25 GHz electron cycrotron resonance (ECR) ion source, and are mass analyzed and focused at the collision center.

Electron scattering from HOPG

Electron images on the two dimensional detector. Images are on the concentric circles and its center is the image point of the collision center. Innermost image is for the electrons with energy of 110 eV and outermost image is for 92 eV electrons. Bright spots are from the electrons scattered at mirror reflection angle, in the present case 75° with respect to the incident electron direction.
